Introduction

Background

New York City is the most populous city in the United States, home to the headquarters of the United Nations and an important center for international diplomacy. It just might be the most diverse city on the planet, as it is home to over

8.6 million people and over 800 languages.

As quoted in an article - What Food Tells Us About Culture

"Traditional cuisine is passed down from one generation to the next. It also operates as an expression of cultural identity. Immigrants bring the food of their countries with them wherever they go and cooking traditional food is a way of preserving their culture when they move to new places."

Problem

Undoubtedly, Food Diversity is an important part of an ethnically diverse metropolis. The idea of this project is to categorically segment the neighborhoods of New York City into major clusters and examine their cuisines. A desirable intention is to examine the neighborhood cluster's food habits and taste. Further examination might reveal if food has any relationship with the diversity of a neighborhood. This project will help to understand the diversity of a neighborhood by leveraging venue data from Foursquare's 'Places API' and 'k-means clustering' unsupervised machine learning algorithm. Exploratory Data Analysis (EDA) will help to discover further about the culture and diversity of the neighborhood.

Stakeholders

This quantifiable analysis can be used to understand the distribution of different cultures and cuisines over 'the most diverse city on the planet – New York City'. Also, it can be utilized by a new food vendor who is willing to open his or her restaurant. Or by a government authority to examine and study their city's culture diversity better.

Data

To examine the above said, following data sources will be used:

New York City Dataset

Link: https://geo.nyu.edu/catalog/nyu_2451_34572

This New York City Neighborhood Names point file was created as a guide to New York City's neighborhoods that appear on the web resource, 'New York: A City of Neighborhoods.' Best estimates of label centroids were established at a 1:1,000 scale, but are ideally viewed at a 1:50,000 scale. This dataset will provide the addresses of neighborhood of NYC in json format. An extract of the json is as follows:

```
{'type': 'Feature',
'id': 'nyu_2451_34572.306',
'geometry': {'type': 'Point',
'coordinates': [-74.08173992211962, 40.61731079252983]},
'geometry_name': 'geom',
'properties': {'name': 'Fox Hills',
'stacked': 2,
'annoline1': 'Fox',
'annoline2': 'Hills',
'annoline3': None,
'annoangle': 0.0,
'borough': 'Staten Island',
'bbox': [-74.08173992211962,
```

Foursquare API

Link: https://developer.foursquare.com/docs

Foursquare API, a location data provider, will be used to make RESTful API calls to retrieve data about venues in different neighborhoods. This is the link to <u>Foursquare Venue Category Hierarchy</u>. Venues retrieved from all the neighborhoods are categorized broadly into 'Arts & Entertainment', 'College & University', 'Event', 'Food', 'Nightlife Spot', 'Outdoors & Recreation', etc. An extract of an API call is as follows:

```
'categories': [{'id': '4bf58dd8d48988d110941735',
'name': 'Italian Restaurant',
'pluralName': 'Italian Restaurants',
'shortName': 'Italian',
'icon': {'prefix': 'https://ss3.4sqi.net/img/categories_v2/food/italian_',
'suffix': '.png'},
'primary': True}],
'verified': False,
'stats': {'tipCount': 17},
'url': 'http://eccorestaurantny.com',
'price': {'tier': 4, 'message': 'Very Expensive', 'currency'
```

Methodology

Download and Explore New York City Dataset

In order to segment the neighborhoods of New York City, a dataset is required that contains the 5 boroughs and the neighborhoods, that exist in each borough, with respective latitude and longitude coordinates. This dataset is downloaded using the mentioned URL.

Once the .json file is downloaded, it is analyzed to understand the structure of the file. A python dictionary is returned by the URL and all the relevant data is found to be in the features key, which is basically a list of the neighborhoods. The dictionary is transformed, into a pandas dataframe, by looping through the data and filling the dataframe rows one at a time using the following depicted loop.

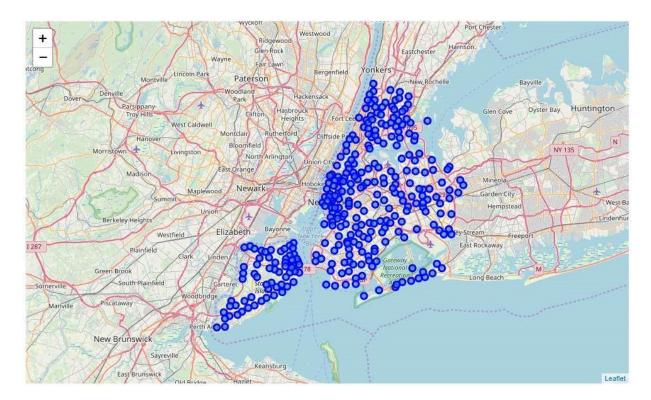

As a result, a dataframe is created with Borough, Neighborhood, Latitude and Longitude details of the New York City's neighborhood.

| | Borough | Neighborhood | Latitude | Longitude |
|---|---------|--------------|-----------|------------|
| 0 | Bronx | Wakefield | 40.894705 | -73.847201 |
| 1 | Bronx | Co-op City | 40.874294 | -73.829939 |
| 2 | Bronx | Eastchester | 40.887556 | -73.827806 |
| 3 | Bronx | Fieldston | 40.895437 | -73.905643 |
| 4 | Bronx | Riverdale | 40.890834 | -73.912585 |

Upon analysis, it is found that the dataframe consists of 5 boroughs and 306 neighborhoods.

Further, 'geopy' library is used to get the latitude and longitude values of New York City, which was returned to be Latitude: 40.71, Longitude: -74.01.

The curated dataframe is then used to visualize by creating a map of New York City with neighborhoods superimposed on top. The following depiction is a map generated using python 'folium' library.

RESTful API Calls to Foursquare

The Foursquare API is used to explore the neighborhoods and segment them. To access the API, 'CLIENT_ID', 'CLIENT_SECRET' and 'VERSION' is defined.

There are many endpoints available on Foursquare for various GET requests. But, to explore the cuisines, it is required that all the venues extracted are from 'Food' category. Foursquare Venue Category Hierarchy is retrieved using the following code block:

```
url = 'https://api.foursquare.com/v2/venues/categories?&client_id={}&client_secret={}&v={}'.format(
    CLIENT_ID,
    CLIENT_SECRET,
    VERSION)
category_results = requests.get(url).json()
```

The returned request is further analyzed:

```
for key, value in category_results['response']['categories'][0].items():
    print(key, len(str(value)))

id 24
name 20
pluralName 20
shortName 20
icon 98
categories 15910
```

Upon analysis, it is found that there are 10 major or parent categories of venues, under which all the other sub-categories are included. Following depiction shows the 'Category ID' and 'Category Name' retrieved from API:

```
for data in category_list:
    print(data['id'], data['name'])

4d4b7104d754a06370d81259    Arts & Entertainment
4d4b7105d754a06372d81259    College & University
4d4b7105d754a06373d81259    Event
4d4b7105d754a06377d81259    Food
4d4b7105d754a06377d81259    Outdoors & Recreation
4d4b7105d754a06375d81259    Professional & Other Places
4e67e38e036454776db1fb3a    Residence
4d4b7105d754a06379d81259    Shop & Service
4d4b7105d754a06379d81259    Travel & Transport
```

As said earlier, the 'FOOD' category in the above depiction is the matter of interest. A function is created to return a dictionary with 'Category ID' & 'Category Name' of 'Food' & it's subcategories.

```
# function to flatten a 'parent_id' category, returns all categories if checkParentID = False

def flatten_Hierarchy(category_list, checkParentID, category_dict, parent_id = ''):
    for data in category_list:

    if checkParentID == True and data['id'] == parent_id:
        category_dict[data['id']] = data['name']
        flatten_Hierarchy(category_list = data['categories'], checkParentID = False, category_dict = category_dict)

    elif checkParentID == False:
        category_dict[data['id']] = data['name']
        if len(data['categories']) != 0:
              flatten_Hierarchy(category_list = data['categories'], checkParentID = False, category_dict = category_dict)

    return category_dict
```

This above function takes the parent 'Category ID' and returns the 'Category Name' and 'Category ID' of all the sub-categories.

```
category_dict
{'4d4b7105d754a06374d81259': 'Food',
    'S03288a091d4c4b30a586d67': 'Afghan Restaurant',
    '4bf58dd849988d10a947735': 'Ethiopian Restaurant',
    '4bf58dd849988d10a941735': 'Mercian Restaurant',

    '52a73a63cf9994f4e043bfe': 'Hakka Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hong Kong Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hong Kong Restaurant',
    '52a73a63cf9994f4e043bfe': 'Huaiyang Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hanan Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hanan Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hanan Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hanan Restaurant',
    '52a73a63cf9994f4e043bfe': 'Hanan
```

To further understand the results of GET Request, the first neighborhood of the 'New York City' dataset is explored. The first neighborhood returned is 'Wakefield' with Latitude 40.89 and Longitude -73.85.

Then, a GET request URL is created to search for Venue with 'Category ID' = '4d4b7105d754a06374d81259', which is the 'Category ID' for 'Food', and radius = 500 meters.

```
LIMIT = 1 # Limit of number of venues returned by Foursquare API
radius = 500 # define radius
categoryId = '4d4b7105d754a06374d81259' # category ID for "Food"

# create URL

url = 'https://api.foursquare.com/v2/venues/search?&client_id={}&client_secret={}&v={}&l={},{}&radius={}&categoryId={}&limit={}'.fc
CLIENT_ID,
CLIENT_SECRET,
VERSION,
neighborhood_latitude,
neighborhood_longitude,
radius,
categoryId,
LIMIT)
url # display URL
```

The returned request is then examined, which is as follows:

```
results['response']['venues']
[{'id': '4c783cef3badb1f7e4244b54',
   'name': 'Carvel Ice Cream',
   'location': {'address': '1006 E 233rd St',
    'lat': 40.890486685759605,
    'lng': -73.84856772568665,
    'labeledLatLngs': [{'label': 'display',
      'lat': 40.890486685759605,
'lng': -73.84856772568665}],
    'distance': 483,
    'postalCode': '10466',
'cc': 'US',
    'city': 'Bronx',
'state': 'NY',
     'country': 'United States',
    'formattedAddress': ['1006 E 233rd St',
      'Bronx, NY 10466',
   'United States']},
'categories': [{'id': '4bf58dd8d48988d1c9941735',
      'name': 'Ice Cream Shop',
  name : Ice Cream Snop ,
'pluralName': 'Ice Cream Shops',
'shortName': 'Ice Cream',
'icon': {'prefix': 'https://ss3.4sqi.net/img/categories_v2/food/icecream_',
'suffix': '.png'},
'primary': True}],
'referralId': 'v-1571614359',
   'hasPerk': False}]
```

The request returned the 'Category Name' of the venue as 'Carvel Ice Cream' which is of 'Food' category.

As, the aim is to segment the neighborhoods of New York City with respect to the 'Food' in its vicinity, it is further required to fetch this data from all the 306 neighborhoods' venues.

To overcome the redundancy of the process followed above, a function 'getNearbyFood' is created. This functions loop through all the neighborhoods of New York City and creates an API request URL with radius = 500, LIMIT = 100. By limit, it is defined that maximum 100 nearby venues should be returned. Further, the GET request is made to Foursquare API and only relevant information for each nearby venue is extracted from it. The data is then appended to a python 'list'. Lastly the python 'list' is unfolded or flattened to append it to dataframe being returned by the function.

It is inquisitive to know that Foursquare API returns all the sub-categories, if a toplevel category is specified in the GET Request.

```
def getNearbyFood(names, latitudes, longitudes, radius=1000, LIMIT=500):
           not_found = 0
print('***Start', end='')
            venues list=[]
            for name, lat, lng in zip(names, latitudes, longitudes):
                       print(' .', end='')
                       # create the API request URL
                        wrl = "https://api.foursquare.com/v2/venues/search?&client_id={}\&client_secret={}\&v={}\&ll={},{}\&radius={}\&categoryId={}\&limt_secret={}\&v={}\&ll={},{}\&radius={}\&categoryId={}\&limt_secret={}\&v={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&radius={}\&r
                                  CLIENT ID,
                                    CLIENT SECRET.
                                    VERSION,
                                    lat,
                                   lng,
                                    radius,
                                      "4d4b7105d754a06374d81259", # "Food" category id
                      try:
# make the GET request
                                  results = requests.get(url).json()['response']['venues']
                                   # return only relevant information for each nearby venue
                                    venues list.append([(
                                                name,
                                                lat.
                                                lng,
v['name'],
                                              v['location']['lat'],
v['location']['lng'],
v['categories'][0]['name']) for v in results])
                        except:
                                    not found += 1
            nearby_venues = pd.DataFrame([item for venue_list in venues_list for item in venue_list])
            nearby_venues.columns = ['Neighborhood',
                                                        'Neighborhood Latitude'
                                                        'Neighborhood Longitude'
                                                        'Venue'
                                                        'Venue Latitude'
                                                       'Venue Longitude',
                                                       'Venue Category']
           print("\nDone*** with {} venues with incompelete information.".format(not_found))
            return(nearby_venues)
```

Pickle

Pickle is a very important and easy-to-use library. It is used to serialize the information retrieved from GET requests, to make a persistent '.pkl' file. This file can later be described to retrieve an exact python object structure. This is a crucial

step as it will counter any redundant requests to the Foursquare API, which is chargeable over the threshold limits.

The returned 'dataframe' is as follows:

| | Neighborhood | Neighborhood Latitude | Neighborhood Longitude | Venue | Venue Latitude | Venue Longitude | Venue Category |
|---|--------------|-----------------------|------------------------|------------------|----------------|-----------------|----------------------|
| 0 | Wakefield | 40.894705 | -73.847201 | Lollipops Gelato | 40.894123 | -73.845892 | Dessert Shop |
| 1 | Wakefield | 40.894705 | -73.847201 | Pitman Deli | 40.894149 | -73.845748 | Food |
| 2 | Wakefield | 40.894705 | -73.847201 | Carvel Ice Cream | 40.890487 | -73.848568 | Ice Cream Shop |
| 3 | Wakefield | 40.894705 | -73.847201 | Burger King | 40.895532 | -73.856436 | Fast Food Restaurant |
| 4 | Wakefield | 40.894705 | -73.847201 | Dunkin' | 40.890459 | -73.849089 | Donut Shop |

As of now, two python 'dataframe' are created:

- 1. 'neighborhoods' which contains the Borough, Neighborhood, Latitude and Longitude details of the New York City's neighborhood, and
- 2. 'nyc_venues' which is a merger between 'neighborhoods' dataframe and its 'Food' category venues searched with 'Radius' = 500 meters and 'Limit' = 100. Also, each venue has its own Latitude, Longitude and Category.

Exploratory Data Analysis

The merged dataframe 'nyc_venues' has all the required information. The size of this dataframe is determined, and it is found that there are total 14,047 venues.

Now, it is important to find out that how many unique categories can be curated from all the returned venues. There are 194 such categories, with most occurring venues as follows:

```
print('There are {} uniques categories.'.format(len(nyc_venues['Venue Category'].unique())))
nyc_venues.groupby('Venue Category')['Venue Category'].count().sort_values(ascending=False)
There are 194 uniques categories.
Venue Category
Deli / Bodega
                                            1136

Data Cleaning

It is crucial to understand that the point of interest in the project is to understand the cultural diversity of a neighborhood by clustering it categorically, using the venues' categories. Thus, it is important to remove all the venues from the 'dataframe' which have generalized categories. Here, by generalized, it means that these categorized venues are common across different cultures and food habits. Example of categories of this type of venues are Coffee Shop, Cafe, etc.

So, firstly all the unique categories are fed into a python 'list'.

```
# list all the categories
unique_categories = nyc_venues['Venue Category'].unique().tolist()
unique categories
['Dessert Shop'.
 Food',
'Ice Cream Shop',
 'Fast Food Restaurant',
 'Donut Shop',
 'Caribbean Restaurant',
 'Bakery',
 'Sandwich Place',
 'Italian Restaurant',
 'Comfort Food Restaurant',
 'Fried Chicken Joint',
 'Deli / Bodega',
 'Food Truck'
 'Chinese Restaurant',
 'Pizza Place',
 'Southern / Soul Food Restaurant',
 'Halal Restaurant',
 'Asian Restaurant',
 'Bagel Shop',
'American Restaurant',
 'Burger Joint',
'Restaurant',
 'Mexican Restaurant'.
 'Seafood Restaurant',
 'Frozen Yogurt Shop'
 'Spanish Restaurant'
```

Then, manually the categories are determined to be 'general' (as explained above). This data pre-preparation totally depends upon the 'Data Analyst' discretion and can be modified as required. Following are the categories listed as 'general':

A simple subtraction of two python 'list' i.e 'unique_categories' and 'general_categories' gives a 'list' of all the categories which are required for further analysis.

Following image depicts the result of the above activity:

```
# fetch all the required food categories
food_categories = list(set(unique_categories) - set(general_categories))
food_categories
['Paella Restaurant',
 Brazilian Restaurant',
 'Steakhouse'.
 'Mexican Restaurant'.
 'Vegetarian / Vegan Restaurant',
 'Italian Restaurant',
 'Peruvian Restaurant',
 'Jewish Restaurant',
'African Restaurant'
 'Ukrainian Restaurant'
 'Sri Lankan Restaurant'
 'Mediterranean Restaurant',
 'Caucasian Restaurant',
 'English Restaurant'
 'American Restaurant'.
 'Korean Restaurant',
 'Vietnamese Restaurant',
 'Cantonese Restaurant',
 'Tapas Restaurant',
 'Hong Kong Restaurant',
 'Persian Restaurant',
 'Dosa Place',
 'Greek Restaurant',
 'Australian Restaurant',
 'Himalayan Restaurant',
 'Taiwanese Restaurant'.
 'Seafood Restaurant'.
 'Salvadoran Restaurant'
 'Japanese Restaurant',
 'Venezuelan Restaurant',
 'Ramen Restaurant',
```

The python 'list' curated above, is used to remove all the venues with categories not in 'food categories', and the following dataframe is retrieved:

| İ | ndex | Neighborhood | Neighborhood Latitude | Neighborhood Longitude | Venue | Venue Latitude | Venue Longitude | Venue Category |
|---|------|--------------|--------------------------|---------------------------|--|-------------------|--------------------|-------------------------|
| i | 3 | Wakefield | 40.894705 | -73.847201 | Burger King | 40.895532 | -73.856436 | Fast Food Restaurant |
| | 5 | Wakefield | 40.894705 | -73.847201 | Cooler Runnings Jamaican Restaurant Inc | 40.898276 | -73.850381 | Caribbean Restaurant |
| | 9 | Wakefield | 40.894705 | -73.847201 | McDonald's | 40.902645 | -73.849485 | Fast Food Restaurant |
| | 10 | Wakefield | 40.894705 | -73.847201 | Ripe Kitchen & Bar | 40.898152 | -73.838875 | Caribbean Restaurant |
| | 11 | Wakefield | 40.894705 | -73.847201 | Frank and Johnies | 40.905019 | -73.858392 | Italian Restaurant |

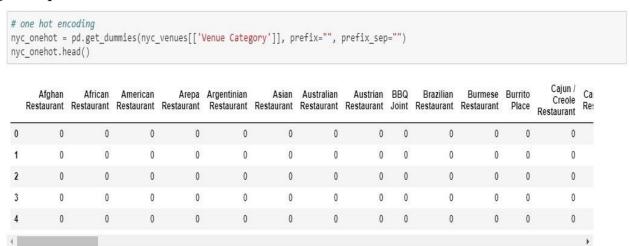

Again, the number of unique categories is examined, and it is found that there are only 92 of them, as compared to 194 earlier. That means, almost 50% of the data was a noise for the analysis. This essential step, data cleaning, helped to capture the data points of interest.

Feature Engineering

Now, each neighborhood is analyzed individually to understand the most common cuisine being served within its 500 meters of vicinity.

The above process is taken forth by using 'one hot encoding' function of python 'pandas' library. One hot encoding converts the categorical variables (which are

'Venue Category') into a form that could be provided to ML algorithms to do a better job in prediction.

Upon converting the categorical variables, as shown above, 'Neighborhood' column is added back which results into the following:

```
# move neighborhood column to the first column
Neighborhood = nyc_onehot['Neighborhood']

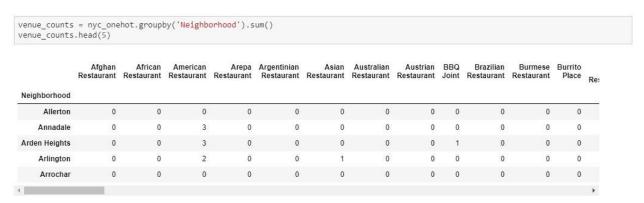

nyc_onehot.drop(labels=['Neighborhood'], axis=1,inplace = True)
nyc_onehot.insert(0, 'Neighborhood', Neighborhood)

nyc_onehot.head()
```

| | Neighborhood | Afghan Restaurant | African Restaurant | American Restaurant | Arepa Restaurant | Argentinian Restaurant | Asian Restaurant | | Austrian Restaurant | BBQ Joint | Brazilian Restaurant | Burmese Restaurant | Burrito Place |
|---|--------------|----------------------|-----------------------|------------------------|---------------------|---------------------------|---------------------|---|------------------------|--------------|-------------------------|-----------------------|------------------|
| 0 | Wakefield | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | Wakefield | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | Wakefield | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 3 | Wakefield | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | Wakefield | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | | | | | | | | | | | | | • |

The size of the new dataframe 'nyc_onehot' is examined and it is found that there are around 6,846 data points all together.

Further, number of venues of each category in each neighborhood are counted.

It is observed that, in the first five neighborhoods of the dataframe, 'Annadale', 'Arden Heights' and 'Arlington' has 3, 3, 2 'American Restaurant' in its 500 meters vicinity.

The top 10 'Venue Categories' can also be found by counting their occurrences. This analysis is depicted below which shows that 'Korean Restaurant', 'Chinese Restaurant', 'Caribbean Restaurant', 'Indian Restaurant', and 'Fast Food Restaurant' are among the top 5.

| | count | mean | std | min | 25% | 50% | 75% | max |
|-------------------------|-------|----------|----------|-----|-----|-----|-----|------|
| Korean Restaurant | 302.0 | 0.291391 | 1.828491 | 0.0 | 0.0 | 0.0 | 0.0 | 29.0 |
| Chinese Restaurant | 302.0 | 2.049669 | 2.083199 | 0.0 | 1.0 | 2.0 | 3.0 | 17.0 |
| Caribbean Restaurant | 302.0 | 1.188742 | 2.785965 | 0.0 | 0.0 | 0.0 | 1.0 | 16.0 |
| Indian Restaurant | 302.0 | 0.324503 | 1.123885 | 0.0 | 0.0 | 0.0 | 0.0 | 15.0 |
| Fast Food Restaurant | 302.0 | 2.198675 | 2.054150 | 0.0 | 1.0 | 2.0 | 3.0 | 11.0 |
| Italian Restaurant | 302.0 | 1.801325 | 1.983386 | 0.0 | 0.0 | 1.0 | 3.0 | 11.0 |
| Pizza Place | 302.0 | 3.569536 | 2.190314 | 0.0 | 2.0 | 3.0 | 5.0 | 10.0 |
| Seafood Restaurant | 302.0 | 0.513245 | 0.849950 | 0.0 | 0.0 | 0.0 | 1.0 | 7.0 |
| New American Restaurant | 302.0 | 0.357616 | 0.745702 | 0.0 | 0.0 | 0.0 | 0.0 | 6.0 |
| Thai Restaurant | 302.0 | 0.311258 | 0.726210 | 0.0 | 0.0 | 0.0 | 0.0 | 6.0 |

Data Visualization

These top 10 categories are further plotted individually on bar graph using python 'seaborn' library. The following code block creates the graph of top 10 neighborhoods for a category.

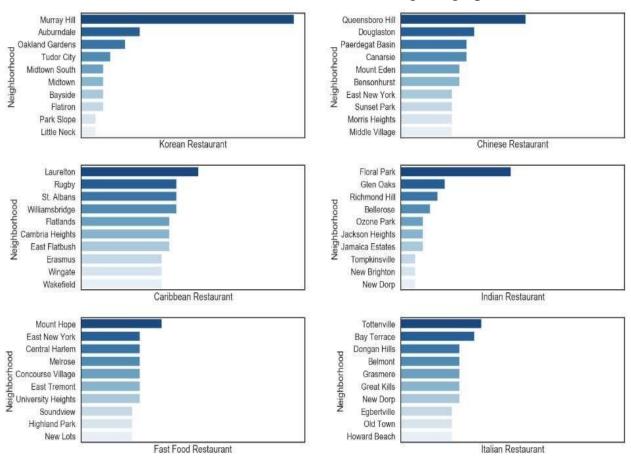

```
import seaborn as sns
import matplotlib.pyplot as plt

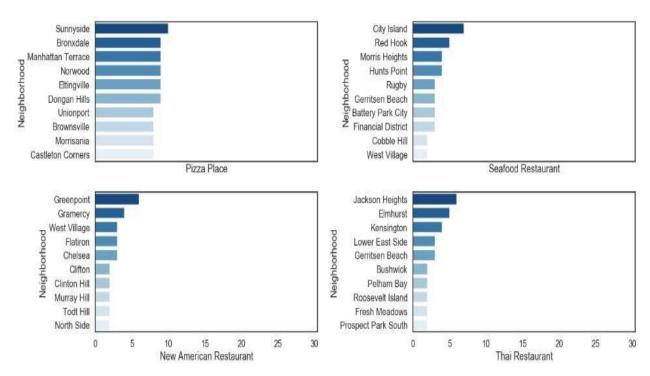

fig, axes =plt.subplots(5, 2, figsize=(20,20), sharex=True)
axes = axes.flatten()
object_bol = df.dtypes == 'object'

for ax, category in zip(axes, venue_top10_list):
    data = venue_counts[[category]].sort_values([category], ascending=False)[0:10]
    pal = sns.color_palette("Blues", len(data))
    sns.barplot(x=category, y=data.index, data=data, ax=ax, palette=np.array(pal[::-1]))

plt.tight_layout()
plt.show()
```

The result of the above code block returns the following bar graphs:

Next, the rows of the neighborhood are grouped together and the frequency of occurrence of each category is calculated by taking the mean.

| | Neighborhood | Afghan Restaurant | African Restaurant | American Restaurant | Arepa Restaurant | Argentinian Restaurant | Asian Restaurant | Australian Restaurant | Austrian Restaurant | BBQ Joint | Brazilian Restaurant | Burmese Restaurant | Burri Pla |
|---|---------------|----------------------|-----------------------|------------------------|---------------------|---------------------------|---------------------|--------------------------|------------------------|--------------|-------------------------|-----------------------|--------------|
| 0 | Allerton | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | C |
| 1 | Annadale | 0.0 | 0.0 | 0.176471 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | (|
| 2 | Arden Heights | 0.0 | 0.0 | 0.176471 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.058824 | 0.0 | 0.0 | 0 |
| 3 | Arlington | 0.0 | 0.0 | 0.105263 | 0.0 | 0.0 | 0.052632 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0 |
| 4 | Arrochar | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0.000000 | 0.0 | 0.0 | 0 |

As the limit is set to be 100, there will be many venues being returned by the Foursquare API. But a neighborhood food habit can be defined by the top 5 venues in its vicinity. Following 'for' loop creates a dataframe to record the abovementioned data points:

```
num_top_venues = 5
indicators = ['st', 'nd', 'rd']

# create columns according to number of top venues
columns = ['Neighborhood']
for ind in np.arange(num_top_venues):
    try:
        columns.append('{}} Most Common Venue'.format(ind+1, indicators[ind]))
    except:
        columns.append('{}th Most Common Venue'.format(ind+1))

# create a new dataframe
neighborhoods_venues_sorted = pd.DataFrame(columns=columns)
neighborhoods_venues_sorted['Neighborhood'] = nyc_grouped['Neighborhood']
```

Further, the above created dataframe is fed with the top 5 most common venues categories in the respective neighborhood.

```
for ind in np.arange(nyc_grouped.shape[0]):
    neighborhoods_venues_sorted.iloc[ind, 1:] = return_most_common_venues(nyc_grouped.iloc[ind, :], num_top_venues)
neighborhoods_venues_sorted.head()
```

| | Neighborhood | 1st Most Common Venue | 2nd Most Common Venue | 3rd Most Common Venue | 4th Most Common Venue | 5th Most Common Venue |
|---|---------------|-----------------------|-----------------------|-----------------------|---------------------------|-----------------------|
| 0 | Allerton | Mexican Restaurant | Fried Chicken Joint | Pizza Place | Chinese Restaurant | Fast Food Restaurant |
| 1 | Annadale | Pizza Place | American Restaurant | Sushi Restaurant | Italian Restaurant | Japanese Restaurant |
| 2 | Arden Heights | Pizza Place | American Restaurant | Italian Restaurant | Mexican Restaurant | Chinese Restaurant |
| 3 | Arlington | Pizza Place | Fast Food Restaurant | American Restaurant | Peruvian Restaurant | Spanish Restaurant |
| 4 | Arrochar | Italian Restaurant | Pizza Place | Steakhouse | Middle Eastern Restaurant | Chinese Restaurant |

Machine Learning

'k-means' is an unsupervised machine learning algorithm which creates clusters of data points aggregated together because of certain similarities. This algorithm will be used to count neighborhoods for each cluster label for variable cluster size.

To implement this algorithm, it is very important to determine the optimal number of clusters (i.e. k). There are 2 most popular methods for the same, namely 'The Elbow Method' and 'The Silhouette Method'.

The Elbow Method

The Elbow Method calculates the sum of squared distances of samples to their closest cluster center for different values of 'k'. The optimal number of clusters is the value after which there is no significant decrease in the sum of squared distances.

Following is an implementation of this method (with varying number of clusters from 1 to 49):

```
Source of squared distances = []

K = range(1,50)

for k in K:

print(k, end=' ')

kmeans = KMeans(n_clusters=k).fit(nyc_grouped_clustering)

sum_of_squared_distances.append(kmeans.inertia_)

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45

plt.plot(K, sum_of_squared_distances, 'bx-')

plt.ylabel('k')

plt.ylabel('sum_of_squared_distances')

plt.title('Elbow Method For Optimal k');

Elbow Method For Optimal k

Elbow Method For Optimal k

0 10 20 30 40 50
```

Sometimes, Elbow method does not give the required result, which happened in this case. As, there is a gradual decrease in the sum of squared distances, optimal number of clusters can not be determined. To counter this, another method can be implemented, as discussed below.

The Silhouette Method

As quoted in Wikipedia – "The Silhouette Method measures how similar a point is to its own cluster (cohesion) compared to other clusters (separation)."

Following is an implementation of this method. As it requires minimum 2 clusters to define dissimilarity number of clusters (i.e. 'k') will vary from 2 to 49:

```
from sklearn.metrics import silhouette score
sil = []
K_sil = range(2,50)
# minimum 2 clusters required, to define dissimilarity
for k in K_sil:
    print(k, end=' ')
    kmeans = KMeans(n_clusters = k).fit(nyc_grouped_clustering)
    labels = kmeans.labels
    sil.append(silhouette_score(nyc_grouped_clustering, labels, metric = 'euclidean'))
2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 4
plt.plot(K_sil, sil, 'bx-')
plt.xlabel('k')
plt.ylabel('silhouette_score')
plt.title('Silhouette Method For Optimal k')
plt.show()
                Silhouette Method For Optimal k
silhouette_score
    0.10
    0.08
```

There is a peak at k = 2, k = 4 and k = 8. Two and four number of clusters will cluster the neighborhoods very broadly. Therefore, number of clusters (i.e. 'k') is chosen to be 8.

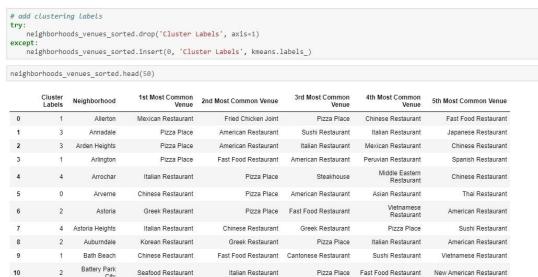

30

k-Means

Following code block runs the k-Means algorithm with number of clusters = 8 and prints the counts of neighborhoods assigned to different clusters:

```
# set number of clusters
kclusters = 8
# run k-means clustering
kmeans = KMeans(init="k-means++", n_clusters=kclusters, n_init=50).fit(nyc_grouped_clustering)
print(Counter(kmeans.labels_))
Counter({2: 91, 3: 53, 1: 50, 4: 50, 0: 26, 5: 20, 6: 11, 7: 1})
```

Further the cluster labels curated are added to the dataframe to get the desired results of segmenting the neighborhood based upon the most common venues in its vicinity:

Now, 'neighborhoods_venues_sorted' is merged with 'nyc_data' to add the Borough, Latitude and Longitude for each neighborhood.

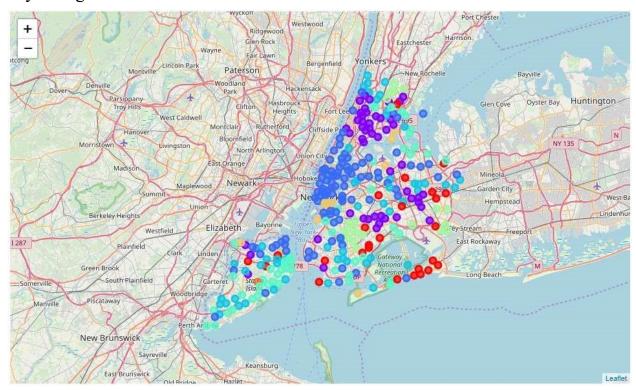

Again, the New York City's neighborhoods are visualized by using the code block as shown, which utilizes the python 'folium' library.

```
# create map
map_clusters = folium.Map(location=[latitude, longitude], zoom_start=10)

# set color scheme for the clusters
colors_array = cm.rainbow(np.linspace(0, 1, kclusters))
rainbow = [colors.rgb2hex(i) for i in colors_array]

# add markers to the map
markers_colors = []
for lat, lon, poi, cluster in zip(nyc_merged['Latitude'], nyc_merged['Longitude'], nyc_merged['Neighborhood'], nyc_merged['Cluster in label = folium.Popup(str(poi) + 'Cluster' + str(cluster), parse_html=True)
folium.CircleMarker(
    [lat, lon],
    radius=5,
    popup=label,
    color=rainbow[cluster-1],
    fill=True,
    fill_color=rainbow[cluster-1],
    fill_opacity=0.7).add_to(map_clusters)
map_clusters
```

Following map is generated which shows the desired segmentation of the New York City's neighborhoods:

Results

Cluster - 0

| | recigiibornood | Venue | Venue | Venue | Venue | Venue | Dorougii | Luttude | Longitude |
|----|--------------------|-------------------------|-------------------------|------------------------------|--------------------|-------------------------|----------|-----------|------------|
| 36 | Brookville | Fried Chicken Joint | Caribbean Restaurant | Pizza Place | Chinese Restaurant | Fast Food Restaurant | Queens | 40.660003 | -73.751753 |
| 41 | Cambria Heights | Caribbean Restaurant | Chinese Restaurant | Latin American Restaurant | Pizza Place | Fast Food Restaurant | Queens | 40.692775 | -73.735269 |
| 68 | Crown Heights | Caribbean Restaurant | Fast Food Restaurant | Pizza Place | French Restaurant | Mexican Restaurant | Brooklyn | 40.670829 | -73.943291 |
| 77 | East Flatbush | Caribbean Restaurant | Pizza Place | Fried Chicken Joint | Chinese Restaurant | Fast Food Restaurant | Brooklyn | 40.641718 | -73.936103 |
| 83 | Eastchester | Caribbean Restaurant | Pizza Place | Fast Food Restaurant | Asian Restaurant | Chinese Restaurant | Bronx | 40.887556 | -73.827806 |
| | | | | | | | | | |

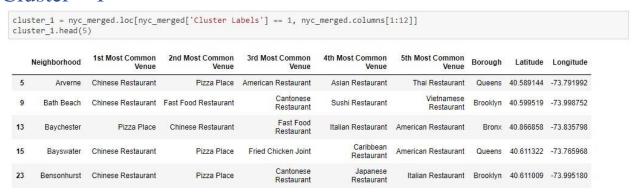

Following are the results of the Cluster -0 analysis:

```
for col in required column:
    print(cluster_0[col].value_counts(ascending = False))
Caribbean Restaurant
Pizza Place
American Restaurant
Fried Chicken Joint
Name: 1st Most Common Venue, dtype: int64
Fast Food Restaurant
Pizza Place
Chinese Restaurant
Caribbean Restaurant
Falafel Restaurant
Fried Chicken Joint
Name: 2nd Most Common Venue, dtvpe: int64
Brooklyn
Oueens
Bronx
Staten Island
Name: Borough, dtype: int64
```

'Caribbean Restaurant' holds a massive accountability for this cluster with 18 occurrences in '1st Most Common Venue' across different neighborhoods followed by 'Fast Food Restaurant' and 'Pizza Place' with 7 occurrences in '2nd Most Common Venue'. Also, 'Caribbean Restaurant' occurs 2 times in '2nd Most Common Venue'. To add on, it is inquisitive to know that majority of these neighborhoods are in 'Brooklyn' borough of New York City.

So, Cluster -0 is a 'Caribbean Restaurant' dominant cluster.

Cluster – 1

Following are the results of the Cluster -1 analysis:

```
for col in required column:
    print(cluster_1[col].value_counts(ascending = False))
Chinese Restaurant
                        18
Pizza Place
                         8
Caribbean Restaurant
Indian Restaurant
Seafood Restaurant
Name: 1st Most Common Venue, dtype: int64
Chinese Restaurant
Caribbean Restaurant
Fast Food Restaurant
American Restaurant
Fried Chicken Joint
Mexican Restaurant
Italian Restaurant
Cantonese Restaurant
Name: 2nd Most Common Venue, dtype: int64
Queens
Brooklyn
Bronx
Staten Island
Name: Borough, dtype: int64
```

'Chinese Restaurant' holds a massive accountability for this cluster with 18 occurrences followed by 'Pizza Place' with 8 occurrences in '1st Most Common Venue' across different neighborhoods. Also, 'Pizza Place' occurs whopping 10 times followed by 'Chinese Restaurant' occurrences of 8 times in '2nd Most Common Venue'. To add on, it is inquisitive to know that majority of these neighborhoods are in 'Queens' borough of New York City.

So, Cluster – 1 is a combination of 'Chinese Restaurant' and 'Pizza Place'.

Cluster – 2

Following are the results of the Cluster -2 analysis:

```
for col in required column:
    print(cluster_2[col].value_counts(ascending = False))
    print("-----
Italian Restaurant
                        27
Pizza Place
                        16
Fast Food Restaurant
                        2
Falafel Restaurant
                         1
Name: 1st Most Common Venue, dtype: int64
Italian Restaurant
Pizza Place
Chinese Restaurant
Asian Restaurant
Mexican Restaurant
Fast Food Restaurant
American Restaurant
Name: 2nd Most Common Venue, dtype: int64
Staten Island
               22
                 10
Queens
Bronx
                 8
Brooklyn
Name: Borough, dtype: int64
```

'Italian Restaurant' holds a massive accountability for this cluster with 27 occurrences followed by 'Pizza Place' with 16 occurrences in '1st Most Common Venue' across different neighborhoods. Also, 'Italian Restaurant' occurs whopping 16 times followed by 'Pizza Place' occurrences of 15 times in '2nd Most Common Venue'. To add on, it is inquisitive to know that majority of these neighborhoods are in 'Staten Island' and 'Queens' borough of New York City.

So, Cluster -2 is a combination of 'Italian Restaurant' and 'Pizza Place'. Pizza is an Italian cuisine, hence cluster -2 can be termed as 'Italian Restaurant' dominant cluster.

Cluster – 3

Following are the results of the Cluster – 3 analysis:

```
for col in required column:
    print(cluster_3[col].value_counts(ascending = False))
Pizza Place
Italian Restaurant
American Restaurant
Korean Restaurant
Seafood Restaurant
Fast Food Restaurant
New American Restaurant
Thai Restaurant
Mexican Restaurant
Greek Restaurant
Vegetarian / Vegan Restaurant
Sushi Restaurant
Middle Eastern Restaurant
Vietnamese Restaurant
Indian Restaurant
Ramen Restaurant
Eastern European Restaurant
Name: 1st Most Common Venue, dtvpe: int64
Italian Restaurant
Pizza Place
American Restaurant
Fast Food Restaurant
French Restaurant
Mexican Restaurant
BBQ Joint
Vietnamese Restaurant
Turkish Restaurant
Middle Eastern Restaurant
Korean Restaurant
Russian Restaurant
Sushi Restaurant
Ramen Restaurant
Noodle House
Indian Restaurant
Japanese Restaurant
Latin American Restaurant
Sri Lankan Restaurant
Shanghai Restaurant
Seafood Restaurant
Asian Restaurant
Thai Restaurant

Name: 2nd Most Common Venue, dtype: int64
Manhattan
                28
Brooklyn
                25
Oueens
                22
Staten Island 12
Bronx
Name: Borough, dtype: int64
```

This is the biggest cluster of all, which means that majority of the neighborhoods are clustered in it. Again, as seen in Cluster -2, 'Pizza Place' and 'Italian Restaurant' holds the top 2 places with respect to the count of occurrences of these categories in '1st Most Common Venue' as well as in '2nd Most Common Venue', But, it is interesting to know that the 3^{rd} place is dominantly held by 'American Restaurant' category, which is why this cluster is segregated from Cluster -2.

To add on, it is inquisitive to know that neighborhoods in this cluster is spread equally across 'Manhattan', 'Brooklyn' and 'Queens' with substantial number of neighborhoods in 'Staten Island'.

So, Cluster -3 is a combination of 'Italian Restaurant', 'Pizza Place' and 'American Restaurant', with 'American Restaurant' showing the dominance to segment this cluster from Cluster -2

Cluster – 4

Following are the results of the Cluster -4 analysis:

```
for col in required column:
    print(cluster_4[col].value_counts(ascending = False))
Pizza Place
Taco Place
Name: 1st Most Common Venue, dtype: int64
Chinese Restaurant
American Restaurant
Japanese Restaurant
Fast Food Restaurant
Italian Restaurant
Mexican Restaurant
Sushi Restaurant
Asian Restaurant
Taco Place
BBQ Joint
Spanish Restaurant
Indian Restaurant
Pizza Place
Caribbean Restaurant
Name: 2nd Most Common Venue, dtype: int64
Staten Island
                20
Queens
                 14
                 11
Brooklyn
Name: Borough, dtype: int64
```

In this cluster, 'Pizza Place' has taken over every other category with shooting 52 occurrences in '1st Most Common Venue' across different neighborhoods followed by 'Chinese Restaurant' with 12 occurrences in '2nd Most Common Venue'. To add on, it is inquisitive to know that majority of these neighborhoods are spread approximately equally across 'Staten Island', 'Queens' and 'Bronx' borough of New York City.

So, Cluster – 4 can be termed as 'Pizza Place' dominant cluster.

Cluster – 5

Following are the results of the Cluster – 5 analysis:

```
for col in required_column:
    print(cluster_5[col].value_counts(ascending = False))
    print("-----")

Italian Restaurant  1
Name: 1st Most Common Venue, dtype: int64

Vietnamese Restaurant  1
Name: 2nd Most Common Venue, dtype: int64

Staten Island  1
Name: Borough, dtype: int64
```

It is clear, that only one neighborhood 'Lighthouse Hill' is curated under this cluster. This segmentation can be understood from the fact that 'Lighthouse Hill' is a tourist attraction for its heritage and is situated at the southernmost of the chain of hills that radiate from the northeast corner of Staten Island. This neighborhood has diverse cuisine in its top 5 most common venues list and hence a separate cluster.

So, Cluster -5 can be termed as exceptional as of now.

Cluster – 6

Following are the results of the Cluster – 6 analysis:

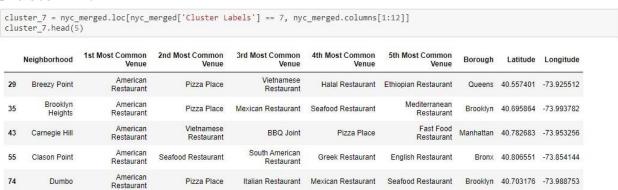

```
for col in required column:
   print(cluster_6[col].value_counts(ascending = False))
Fast Food Restaurant
Pizza Place
                        14
Mexican Restaurant
Chinese Restaurant

                10
Brooklyn
                 9
Manhattan
                 5
Staten Island
                 4
Name: Borough, dtype: int64
```

'Fast Food Restaurant' holds a massive accountability for this cluster with 28 occurrences followed by 'Pizza Place' with 14 occurrences in '1st Most Common Venue' across different neighborhoods. Also, the same proportionate distribution can be seen in '2nd Most Common Venue' occurrence counts.

To add on, it is inquisitive to know that majority of these neighborhoods are in 'Bronx' and 'Queens' borough of New York City.

It is known that, although pizza is an Italian cuisine, it is also a fast food. So, Cluster – 6 can be termed as 'Fast Food Restaurant' dominant cluster.

Cluster – 7

Following are the results of the Cluster -7 analysis:

```
for col in required_column:
    print(cluster_7[col].value_counts(ascending = False))
American Restaurant 14
Pizza Place
Name: 1st Most Common Venue, dtype: int64
Pizza Place
Mexican Restaurant
Italian Restaurant
Seafood Restaurant
Chinese Restaurant
American Restaurant
Fast Food Restaurant
Vietnamese Restaurant
Name: 2nd Most Common Venue, dtype: int64
Manhattan
Brooklyn
                4
Staten Island
               2
Oueens
Bronx
Name: Borough, dtype: int64
```

'American Restaurant' hold a massive accountability for this cluster with 14 occurrences in '1st Most Common Venue' across different neighborhoods. Also, there is a mix of cuisines in the '2nd Most Common Venue'. To add on, it is inquisitive to know that majority of these neighborhoods are in 'Manhattan' and 'Brooklyn' borough of New York City.

So, Cluster – 7 can be termed as 'American Restaurant' dominant cluster.

Discussion

To understand the clusters, three analysis were done, namely:

- 1. Count of 'Borough'
- 2. Count of '1st Most Common Venue'
- 3. Count of '2nd Most Common Venue'

The above information speaks a lot about the ground reality of clustering based on the similarity metrics between the neighborhoods.

Tabulating the results of the k-Mean unsupervised machine learning algorithm:

| | Count of Occurrences within the Cluster | | | | | | | | | |
|---------|---|-----------------------------------|--------------------------|--|--|--|--|--|--|--|
| Cluster | 1 st MostCommonVenue | 2 nd MostCommonVenue | Borough | | | | | | | |
| 0 | Caribbean Restaurant | Fast Food Restaurant, Pizza Place | Brooklyn | | | | | | | |
| 1 | Chinese Restaurant, Pizza Place | Pizza Place, Chinese Restaurant | Queens | | | | | | | |
| 2 | Italian Restaurant, Pizza Place | Italian Restaurant, Pizza Place | Staten Island, Queens | | | | | | | |

| 3 | Pizza Place, Italian Restaurant, American Restaurant | Pizza Place, Italian Restaurant, American Restaurant | Manhattan, Brooklyn, Queens |
|---|---|---|---------------------------------|
| 4 | Pizza Place | Chinese Restaurant | Staten Island, Queens, Bronx |
| 5 | Italian Restaurant | Vietnamese Restaurant | Lighthouse Hill |
| 6 | Fast Food Restaurant, Pizza Place | Fast Food Restaurant, Pizza Place | Bronx, Queens |
| 7 | American Restaurant | Pizza Place | Manhattan, Brooklyn |

Pizza, who does not like it. And it is obvious from the analysis that Pizza Place is the most common venue across all the clusters or neighborhoods. So, as Pizza Place is a ready-to-go place for New York City, it is kept aside to rename the clusters.

Following could be the name of the clusters segmented and curated by k-Means unsupervised machine learning algorithm:

- Cluster 0 Caribbean
- Cluster 1 Chinese
- Cluster 2 Italian
- Cluster 3 Italian American
- Cluster 4 Pizza
- Cluster 5 Mix of Cuisines
- Cluster 6 Fast Food
- Cluster 7 American

Conclusion

On application of Clustering Algorithm, k-Means or others, to a multi-dimensional dataset, a very inquisitive results can be curated which helps to understand and visualize the data. The neighborhoods of New York City were very briefly segmented into eight clusters and upon analysis it was possible to rename them basis upon the categories of venues in and around that neighborhood. Along with the American cuisine, Italian and Chinese are very dominant in New York City and so is the diversity statistics.

The results of this project can be improved and made more inquisitive by using a current New York City's dataset along with API platforms which are more interested in Food Venues (like Yelp, etc.) The scope of this project can be expanded further to understand the dynamics of each neighborhood and suggest a new vendor a

profitable location to open his or her food place. Also, a government authority can utilize it to examine and study their city's culture diversity better.
